

DEBUNKING THE TOP MYTHS OF SOFTWARE QA TESTING

Application testing is undoubtedly a significant step to consider in the software development life cycle. However, it is too often underutilized and overlooked by companies due to various speculations around it.

Let's look at the top myths of software testing and debunk them.

Myth 1:

Testing is expensive and isn't needed in the early stage.

Reality:

Early testing saves both cost and time in many aspects. It's always suggestible to have a testing strategy in the early stage instead of post-development.

Myth 2:

One-time testing is enough and fixes all bugs.

Reality:

Errors are unpredictable, and therefore testing an application post-development doesn't yield good results. You require software testing as long as your application is live.

Myth 3:

Anyone can do software testing with advanced automation tools.

Reality:

Without a deep understanding of product functionality and customer requirements, you can not generate test reports and resolve them.

Myth 4:

QA testing is responsible for product quality.

Reality:

QA testing involves identifying bugs and letting stakeholders know about them. Later, upon their guidelines, they resolve bugs and help in faster product delivery.

Myth 5:

Testing is a time-consuming activity.

Reality:

Software testing time depends on the number of bugs that occur during development. Testing and QA teams have to audit, find, and fix errors timely to ensure better quality.

Myth 6:

Testing is all about finding bugs.

Reality:

It is one of the biggest misconceptions of software testing. Besides finding bugs, software testing involves functional and non-functional testing to validate an application's functionality.

In a nutshell, software testing is a crucial segment that you need to focus on and strategize every time to yield the best results.
